Microsoft Internship

Microsoft AI

In recent years, artificial intelligence (AI) has advanced and become increasingly integrated into various aspects of daily life and technological development. Artificial Intelligence (AI) is a technology that uses computers to perform tasks by learning from patterns. It also processes information to predict outcomes. Generative AI is a type of Artificial Intelligence that uses large language models (LLMs) trained on vast amounts of data to generate text, images, music, videos, or software code. Unlike traditional search engines that retrieve existing information, generative AI creates original responses based on patterns that it has learned. Some popular generative AI tools include Microsoft Copilot, ChatGPT, Google Gemini, Claude, DeepSeek, and many more. These tools can serve as virtual assistants for our daily tasks, such as planning, tutoring, brainstorming, and generating images.

During this internship, we will create AI Agent solutions using Microsoft AI to solve a problem of our choosing. AI agents take generative AI a step further by planning, making decisions within defined rules, and completing multiple tasks to accomplish a specific goal. They can also use multiple tools together to automate complex business processes that would otherwise require multiple manual steps. The five most common types of AI agents are reactive agents, model-based agents, goal-based agents, utility-based agents, and learning agents. They can be autonomous or non-autonomous. Autonomous means they can make decisions and take actions on their own goals, data, and context. Non-autonomous agents require human input and operate within strict rules. Some examples of AI agents used in the real world include IT Help

Desk agents that provide support to users for technical problems, and student support chatbots in the education system that help students with common questions about course-related work.

Artificial Intelligence has become a major part of the Microsoft ecosystem, which can be broken down into components tailored to different users, including everyday users, business users, and developers. Everyday users can improve productivity with Microsoft Copilot and Microsoft 365 Copilot, while businesses can create custom AI agents with Copilot Studio and automate workflows with Power Platform. In addition, developers can use Azure AI, which provides services for applications such as text-to-speech, language translation, image recognition, and more. Azure AI Foundry is a platform for developers to build AI applications, test prompts, and evaluate models. In addition, GitHub Copilot is used to generate code, explain code, write unit tests, fix bugs, and generate documentation.

Overall, artificial intelligence can assist with daily tasks and assignments, allowing our workflows to run much more efficiently and smoothly. In turn, these tools can work together to allow organizations to integrate AI into daily business operations, automate repetitive tasks, and improve collaboration.
